Modeling of photovoltaic sources and their emulation by means of power electronic converters are challenging issues. The former is tied to the knowledge of the electrical behavior of the PV generator; the latter consists in its realization by a suitable power amplifier. This extensive introduction to the modeling of PV generators and their emulation by means of power electronic converters will aid in understanding and improving design and set up of new PV plants. The main benefit of reading Photovoltaic Sources is the ability to face the emulation of photovoltaic generators obtained by the design of a suitable equipment in which voltage and current are the same as in a real source. This is achieved according to the following steps: the source electrical behavior modeling, the power converter design, including its control, for the laboratory emulator. This approach allows the reader to cope with the creation of an indoor

Computers play an important role in the analyzing and designing of modern DC-DC power converters. This book shows how the widely used analysis techniques of averaging and linearization can be applied to DC-DC converters with the aid of computers. Obtained dynamical equations may then be used for control design. The book is composed of two chapters. Chapter 1 focuses on the extraction of control-to-output transfer function. A second-order converter (a buck converter) and a fourth-order converter (a Zeta converter) are studied as illustrative examples in this chapter. Both ready-to-use software packages, such as PLECS(R) and MATLAB(R) programming, are used throughout this chapter. The input/output characteristics of DC-DC converters are the object of considerations in Chapter 2. Calculation of input/output impedance is done with the aid of MATLAB(R) programming in this chapter. The buck, buck-boost, and boost converter are the most popular types of DC-DC converters and used as illustrative examples in this chapter. This book can be a good reference for researchers involved in DC-DC converters dynamics and control.

Power Quality” Special Issue of the journal Energies. It reflects on the latest investigations and the new trends in this field.

At present, power electronic converters are widely used in systems such as shipboard power systems, distributed generation systems and DC microgrids. These devices allow for direct and fast control of the system states: voltages and currents. This is a desirable characteristic, especially when considering smart grid applications. However, the rise in the number of such devices connected to the grid, adds to the inherent nonlinearity of the power system leading to phenomena such as bifurcation and chaos. Further complications arise due to the interactions between the power system and the communication system; two systems that have been historically considered as detached from one another. Due to the growing incentives for smart grid development, the interdependence of these two systems must be recognized and incorporated into existing power electronic converter system models. This work presents models for DC-DC converter systems inclusive of both power system variables and information variables. The effects of network delay on the steady-state and dynamic stability of the overall information-embedded power electronic converter system are analyzed and quantified through proposed metrics. Additionally, uncertainty is introduced into the system model in the form of perturbations in network delay,

The presence of unavoidable disturbances has become an issue concerning power electronic converter modeling and design. These disturbances result in system parameter uncertainties, which may significantly alter predicted performance of a power converter. In this thesis, power electronic converter performance is studied under the influence of random noise. We experimentally verify existence of random noise and measure its statistical properties on the operating characteristics of a switching power converter. Available deterministic approaches do not provide insight into important effects of random noise on dynamics of a power converter. To address this problem, we develop converter models that include the effect of random noise on dynamics of practical converters. We also develop a security index to quantify the converter performance. This index is known as mean first passage time (MFPT). It represents the time for trajectories represented by the converter model, to evolve from an operating point to the boundary of domain of attraction.

In fuel cell applications, design of an appropriate controller and selection of an Ultra-Capacitor require a suitable model of fuel-cell-systems that can adequately represent the significant characteristics of the system. Such a model, using lumped circuit elements, was developed in this thesis via a simple method without requiring fuel cell design parameters. To validate the model, simulation results from the model were compared against the results from experimental setups and satisfactory results were obtained. Later, this model was used in order to design a controller that meets the control objectives, namely, regulation of output voltage and attenuation of load current

variations at the output fuel cell system. Performance of the controller was verified by simulation. High efficiency is an indispensable requirement for fuel cell power conditioners. Finally, in view of this requirement, an analytical method was used in order to calculate power losses in the boost converter and determine factors that influence these losses. This method is helpful in understanding power loss mechanisms in power electronic converters and thus designing high efficient power conditioners for fuel cell systems.

Abstract: Hybrid-Electric Vehicles (HEVs) are an emerging technology in the automotive market. To develop efficient yet powerful HEVs that can be charged easily, it is necessary to use modern concepts of electronic power conversion to design optimum converters. The current project presents the design and development of a proposed converter, and compares its performance to other existing converters commonly used for HEV battery charging. Simulation results and analysis of the proposed converter show that it provides high output power, by having a high output voltage and high output current. The simulations show that the proposed system can provide up to twice the output power of a traditional fly-back converter.

Hardware-in-the-loop (HIL) simulators are prevalent in many industries and are playing a significant role in the design and testing of new equipment. While detailed models of power system components are available for HIL simulators, there is limited knowledge in the area of power electronic converter modeling. Currently available HIL simulators employ simpler models for power electronic converters, based on ideal or averaged switch models. While such models are adequate for system-level performance evaluation and analysis, there are seldom sufficient for the analysis of device-level stresses, electromagnetic interference (EMI), and parasitics, which are especially important at high switching frequencies. This thesis develops device-level models for power electronic converters for HIL simulation. Detailed device-level hardware models are developed for the insulated-gate bipolar transistor (IGBT) and the power diode on the field-programmable gate array (FPGA). The hardware design are fully paralleled using an IEEE 32-bit floating-point precision to achieve the lowest latencies and resource consumption. An efficient variable time-stepping algorithm is proposed for the solution of the nonlinear device equations. Case studies for DC-DC and DC-AC
